CreditWatch EWS: a point-in-time early-warning system for corporate credit

Zeckathon 2026, Problem Statement 02 (Risk & Fraud)

Shivam Verma, Homish Tripathi

Summary

CreditWatch produces a **quarterly watch-list of the 40 riskiest names in an 800-borrower book** (the 5% review budget). Each name carries three plain-language drivers, Altman Z'' / Beneish M / Piotroski F screens, dated soft signals and a review memo. Every input is point-in-time: a number enters only after the date it became public.

Question the judges asked	Our answer	Evidence
Does the distress model work on the benchmark?	Yes. 4-quarter model PR-AUC **0.486** vs 0.070 baseline (6.9x); 8-quarter model **0.395** vs 0.053 (7.4x), untouched hold-out	§2
Could it have flagged the Indian cases in time?	**Mostly no, and we say so.** Pre-registered test, 10 defaulters vs 31 peers: model alone caught **2/10** four quarters ahead, the full overlay **0/10**, and **0/10** eight quarters ahead	§3
Why not, and what would work?	Standalone, condensed statements hide group stress and make the working-capital proxy noisy; rating actions arrive 2 weeks to 4 months before default. Simple debt-service ratios *do* separate defaulters 4 quarters ahead (AUC 0.70 to 0.77, exploratory)	§3.4
Is the 5% budget respected?	Always: hard cap of 40, overflow list, stress trigger	§6
Does the threshold minimise cost?	p* = 1/21 on calibrated probabilities; at a 2% default rate the cost-optimal list is 43 names, so the 40-name cap costs 0.5%; at 4.1% it costs +52%	§6
Could you have tuned on the answers?	No. Models, weights and rules were frozen and committed (SHA-256) before any Indian case was scored; evaluation refuses to run on edited settings	§3.2

The negative Indian result is the most useful finding in this submission. A benchmark-trained model that looks good on paper (PR-AUC 6.9x the baseline) did not transfer to Indian filings, and we show exactly why.

1. System overview

```
filings (dated) --> 39 portable ratios --> lead-matched LightGBM (imputed, calibrated) --> p
Z''/M/F screens + interest cover < 1 ----------------------------------------> overlay
dated soft signals (rating, pledge, auditor, filing delay, related party) -----> overlay
p + overlay --> risk --> rank --> top 40 of 800 + memos  (rank 41+ above p*: overflow list)
```

- `src/model.py`: benchmark training, calibration, hold-out metrics, ablation, model comparison
- `src/indian.py`: point-in-time panel, leakage guard, pre-registered evaluation
- `src/rank.py`: overlay, SHAP drivers, memos, budget simulation
- `src/config.py`: pre-registration freeze and verify
- `src/api.py` + `frontend/`: FastAPI + React app (7 pages); `app.py`: Streamlit; `score_any.py`: score any statements file
- `python run_all.py` rebuilds every number in this report; `python -m pytest -q` runs 40 unit and integration tests.

2. D1: benchmark distress model

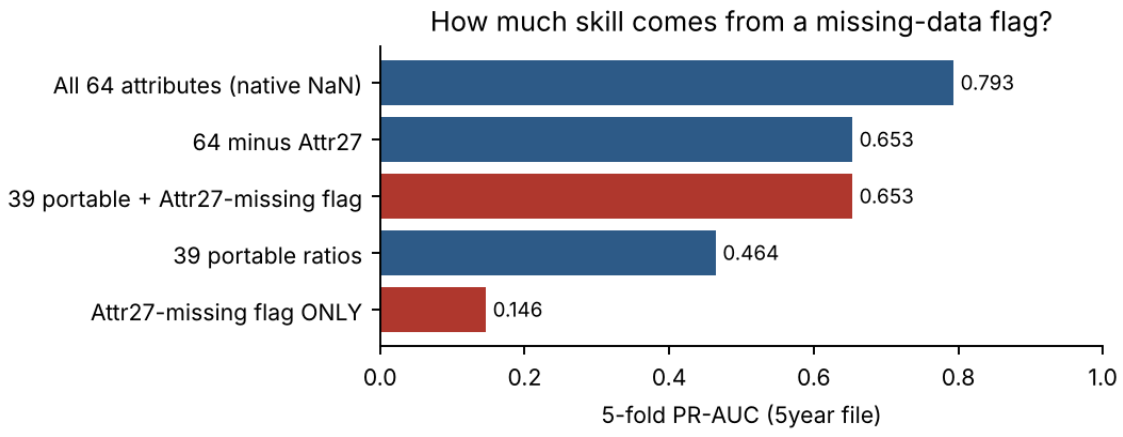

Data. UCI Polish Companies Bankruptcy, all five horizon files (43,405 firm-years, 2,091 bankrupt; counts match UCI). File *k* holds ratios observed (6 − *k*) years before the label.

Lead-matched design. The Indian test asks about 4- and 8-quarter lead, so the 4Q model is trained on the **5year file** (bankrupt within 1 year) and the 8Q model on the **4year file** (within 2 years). The benchmark target therefore matches the test target.

Features. 39 ratios that can be rebuilt from an Indian balance sheet and P&L, mapped one-to-one to UCI attributes (`src/features.py`). There are no absolute amounts (currency- and era-dependent).

Leakage controls. Exact duplicates are removed before the split (60 rows in the 5year file). A stratified 20% hold-out is carved first and used once. Imputer, Platt calibrator and cost threshold are fitted on development folds only.

The missing-data artefact. In the UCI data, missing values cluster in bankrupt firms. Attr27 (operating profit / financial expenses) is missing for 390 firms; 31.5% of them went bankrupt vs 5.2% otherwise, and that *missingness flag alone* reaches PR-AUC 0.146. A native-NaN 64-attribute model scores 0.833, partly by reading “missing” as “bankrupt”. That cannot transfer: a debt-free Indian company has no interest cost. Our production models drop Attr27 and **median-impute every other ratio inside the training folds**, so missingness carries no signal. This costs almost nothing (5-fold PR-AUC 0.429 imputed vs 0.432 native-NaN).

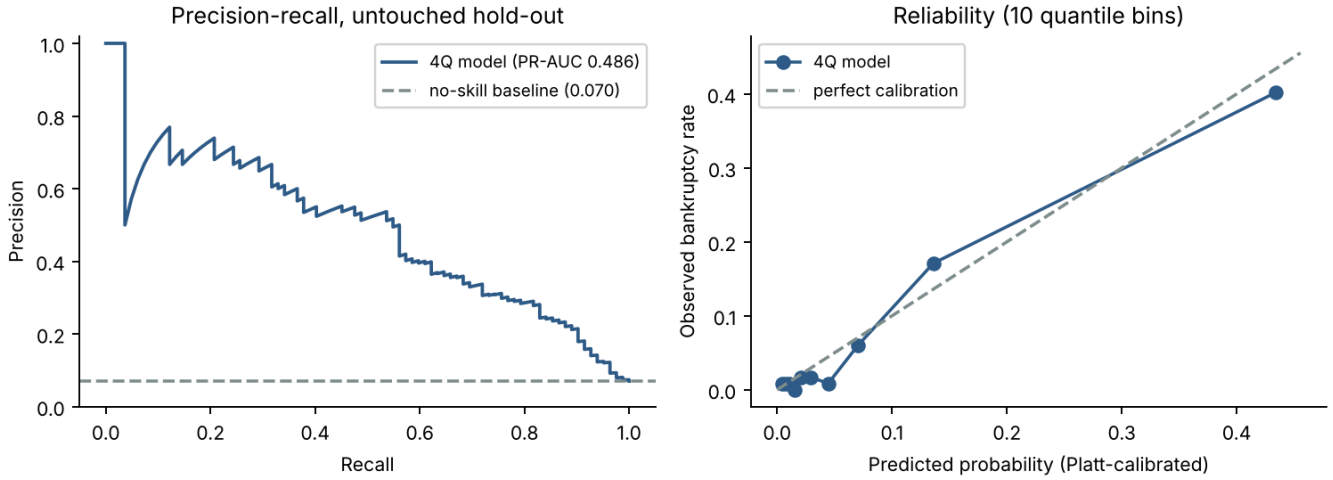

Skill attributable to a missing-data flag

Model selection (identical 5-fold CV on the 4Q development set, PR-AUC): logistic 0.321, random forest 0.375, XGBoost 0.438, LightGBM native-NaN 0.432, **LightGBM median-imputed 0.429 (selected for transferability)**.

Hold-out results.

	4Q model (5year file)	8Q model (4year file)
Hold-out size (bankrupt)	1,170 (82)	1,942 (103)
PR-AUC [95% bootstrap CI]	**0.486** [0.376, 0.609]	**0.395** [0.310, 0.479]
No-skill baseline / lift	0.070 / 6.9x	0.053 / 7.4x
ROC-AUC	0.890	0.846
Brier score (calibrated)	0.047	0.040
Top 5% of hold-out: precision / recall	54% / 39%	37% / 35%
At p* = 1/21: recall / alert rate	90% / 33%	76% / 29%

Benchmark precision-recall and calibration

Caveat: the dataset has no calendar dates or firm IDs, so the hold-out is out-of-sample in firms, not in time. Treat these figures as an upper bound.

3. D2: Indian case test

3.1 Panel

Ten listed defaulters. The event date is the **earliest documented credit event**, each with a source: an exchange filing, rating-agency release, trustee notice or NCLT order (`data/indian/events.csv`).

Defaulter	Event date	Event	Later milestone (not used)
Jet Airways	31 Dec 2018	missed interest + principal to SBI consortium	grounding Apr 2019, CIRP Jun 2019
DHFL	4 Jun 2019	delayed NCD obligations; CP cut to D	RBI supersession Nov 2019
Reliance Capital	9 Sep 2019	NCD coupon paid late; CARE D	RBI supersession Nov 2021
Future Retail	31 Dec 2021	missed Rs 3,494.56 cr principal	CIRP Jul 2022
Coffee Day Enterprises	11 Sep 2019	ICRA BB+ → D (group delays Aug 2019)	founder's death 31 Jul 2019 is not a credit event
Alok Industries	18 Jul 2017	NCLT admits SBI petition	earlier defaults not verified
Bhushan Steel	1 Apr 2015	debenture interest default (trustee notice)	CIRP Jul 2017
Reliance Communications	30 May 2017	CARE and ICRA cut to D	NCLT May 2018
Sintex Industries	31 May 2019	bank-facility delays; NCD default 11 Jun; CARE D	CIRP Apr 2021
IL&FS Transportation Networks	28 Sep 2018	CARE BB → D	the parent IL&FS Ltd was unlisted, so its listed road subsidiary is used

Using the later milestones would have inflated lead time by 3 to 28 months.

31 matched peers. Same sector, listed on the event date, no default found through event + 8 quarters. One peer was dropped because it listed after its event.

Financials. Screener.in standalone statements, 484 company-years. The four defaulters added in our audit are transcribed in `data/indian/screener_raw/`, and every balance sheet adds up (tested). Current assets and liabilities are Screener's condensed "other assets / other liabilities" (a flagged proxy). Unknown items stay missing, never 0. Alok's two 18-month periods are annualised.

Point-in-time rules. Observation = event − 3L months. A fiscal year counts only once FY end + 120 days has passed; SEBI LODR requires audited results within 60 days, so this is conservative. Soft signals count only if dated before the observation and within the prior 365 days. Peers are observed on their defaulter's date. Four tests check this on the real panel.

3.2 Pre-registration

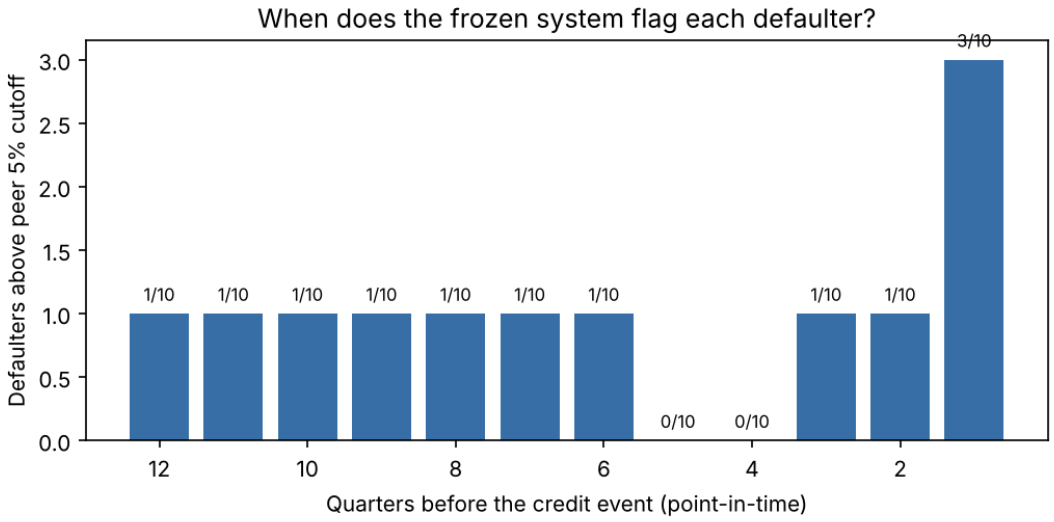

`config/frozen_config.json` pins the model-file SHA-256 hashes, overlay weights, soft-signal rules, lags, lead mapping, cost ratio, capacity and the metric definition. It was **committed before any Indian case was scored** (see the commit history). `indian.evaluate()` verifies the hash and refuses to run if anything differs; this is tested by tampering with a weight. Every change is logged in `docs/DEVIATIONS.md`.

Primary metric. Peers stand in for the performing book. Defaulters are about 2% of a real book, so its 95th percentile is the performing firms' 95th percentile. A defaulter is caught if its score is above the 95th percentile of peer scores at the same lead (the 5% budget). We report Wilson 95% intervals.

3.3 Result: reported as-is

Lead	Model only	Model + Z/M/F	Full (+ soft signals)	Soft signals only
4 quarters	**2/10** [6%, 51%]	0/10 [0%, 28%]	**0/10** [0%, 28%]	1/10 (Future Retail)
8 quarters	**0/10**	0/10	**0/10**	0/10

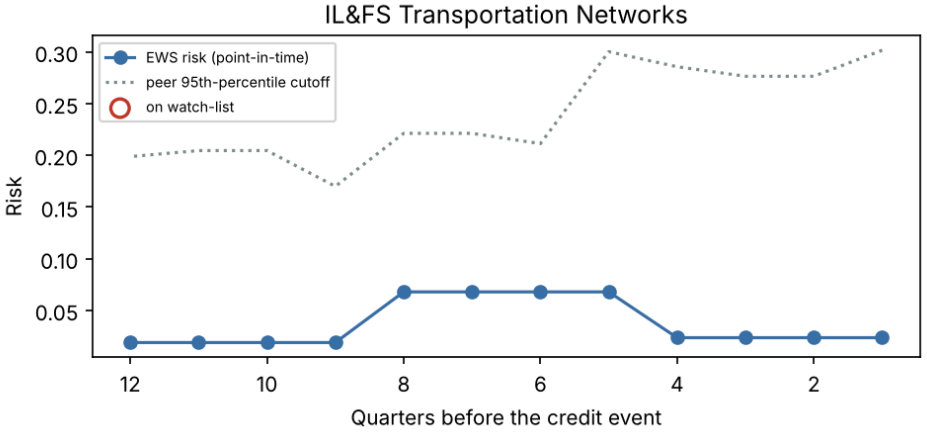

A secondary method (a simulated 800-name book with a Polish background) also gives 0/10, even though it favours Indian firms. **Post-hoc threshold-free AUC, defaulters vs peers: 0.46 at 4Q and 0.46 at 8Q, no better than chance.** Of the 10 defaulters, 3 cross the cutoff one quarter ahead; only Jet Airways is above it from 6 to 12 quarters ahead.

When the frozen system flags each defaulter

3.4 Why it failed, and what does work

1. **Group structures hide the stress.** ITNL and Coffee Day were holding or infrastructure companies whose distress sat in group SPVs and subsidiaries. Their standalone “other assets” are mostly loans to group companies, so they look liquid. ITNL’s risk never rose above 0.07 against a peer cutoff of 0.17 to 0.30.

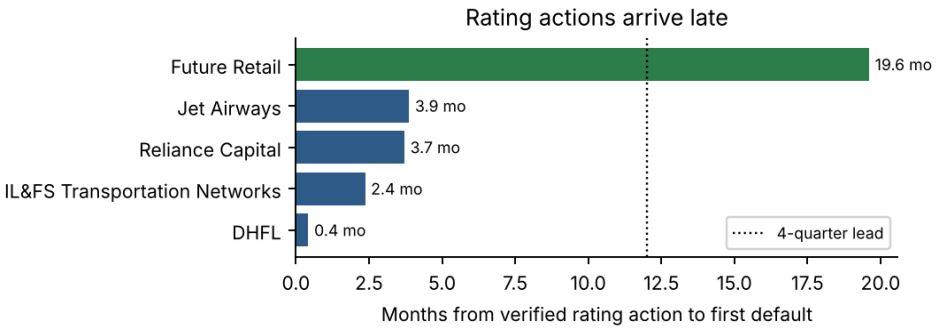

IL&FS Transportation Networks, point-in-time

2. **The condensed-balance-sheet proxy is noise.** On Indian data, WC/TA has AUC 0.48 and the current ratio 0.44. Z’’ (which uses WC) puts healthy peers such as Ashoka Buildcon and

Shoppers Stop (the latter likely because of Ind AS 116 lease liabilities) in the “distress” zone. That raises the cutoff, which is why the overlay *lowered* recall.

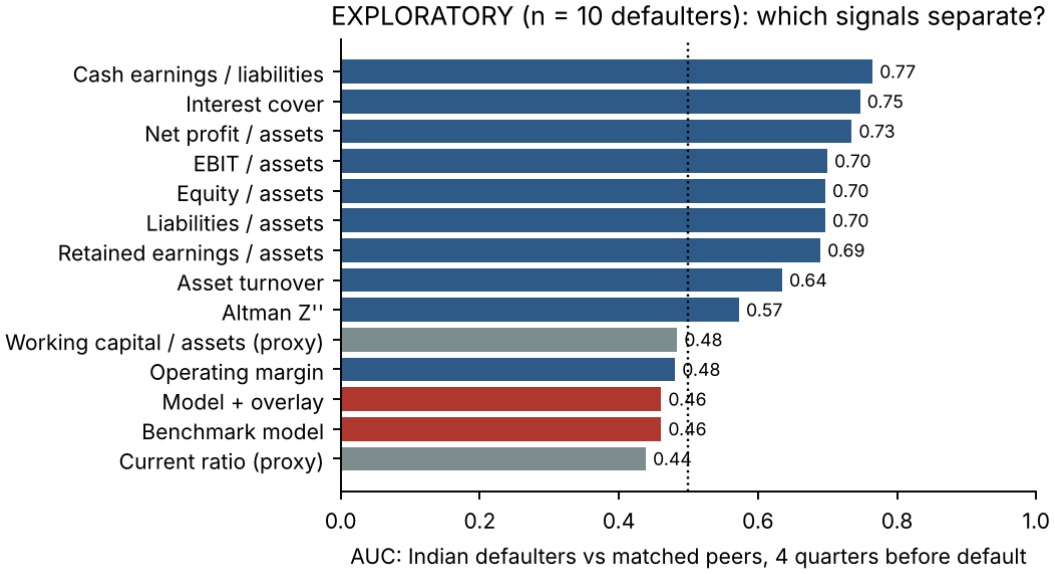

3. **The benchmark model learned non-credit patterns.** SHAP on a synthetic distressed company showed the trees treating costs above sales, negative working capital and negative retained earnings as *safe*. A post-hoc v2 with credit-logic monotone constraints, frozen separately before scoring, did not help: benchmark PR-AUC fell to 0.395 / 0.187 and Indian AUC was 0.37 to 0.43. v1 therefore stays primary and v2 is reported as tested and rejected.

4. **Rating actions are late.** Of the five verified pre-default rating actions, four arrived 2 weeks to 4 months before default. Only Future Retail’s came at least 4 quarters ahead.

Rating actions arrive late

What does separate Indian defaulters (exploratory; read after the frozen results; n = 10; not used to tune anything). Classic debt-service ratios, four quarters before default:

Exploratory univariate AUC

Cash earnings / total liabilities (Beaver’s best single predictor) has AUC 0.77, interest cover 0.75 and ROA 0.73; leverage and equity ratios are about 0.70. **The recommended next step** is an India-trained, monotone debt-service scorecard on *consolidated* statements, validated out-of-time (e.g. fit on the 2015–17 defaults, test on 2018–22). The pipeline, leakage guard and freeze mechanism are already in place for it.

4. D3: forensic screens and soft signals

- **Altman Z’’** (emerging-market version): 6.56 X1 + 3.26 X2 + 6.72 X3 + 1.05 X4. Zones: < 1.10 distress, 1.10–2.60 grey, > 2.60 safe.
- **Beneish M** (8 variables, cutoff −1.78) and **Piotroski F** (9 tests, ≤ 3 weak). All three are checked against hand calculations on a worked example in the tests (Z’’ = 2.270, M = −1.741, F = 3).
- Banks and NBFCs (DHFL, Reliance Capital) skip Z/M/F by design. With Screener data, M and F need COGS, SG&A and share counts, so they are reported as missing rather than guessed.
- **Soft signals** (capped log-odds policy priors, not fitted): rating downgrade or watch-negative, promoter pledge > 50%, auditor red flag, delayed filing, related-party stress. The shipped panel uses five rating actions verified with URLs. An earlier unverified list is kept aside and unused.

5. D4: explanations

Top-3 SHAP drivers come from the model input, rendered as *ratio → firm value vs healthy-peer median → why it matters*. Two rules keep memos honest. Imputed (missing) ratios are never drivers. A driver is written up only if the firm’s value is on the risky side of the median under credit logic, because tree models can attach risk to healthy-looking values. Example: **Jet Airways, four quarters before default** (FY2017 accounts):

> 1. Retained earnings are −52.0% of assets (healthy peers 0.0%); accumulated losses have eroded the equity cushion.
> 2. Long-term funding is 20.5% of assets (healthy peers 63.4%); long assets may be funded with short-term money (ALM risk).
> 3. Sales cover short-term liabilities only 2.14x (healthy peers 5.10x); revenue is small relative to near-term claims.

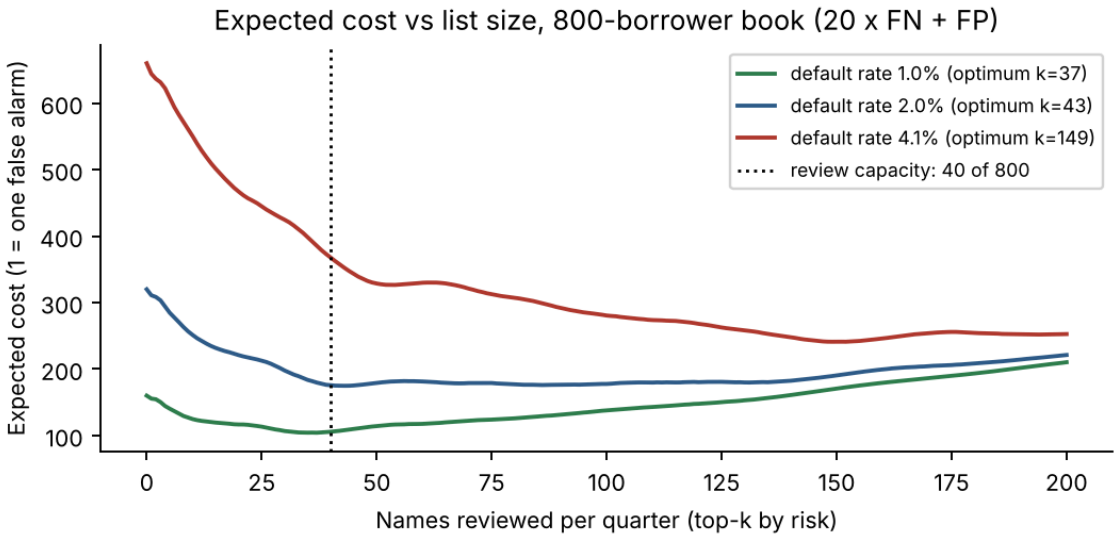

Each memo adds the Z/M/F values, active soft signals and a recommended action.

6. D5: operating policy and cost

Cost. A missed default costs 20, a false alarm 1. For a calibrated probability p, flagging is worth it when $20p > 1 - p$, i.e. **$p > p^* = 1/21 \approx 4.76\%$**. Probabilities are prior-shifted to the bank’s own default rate before applying p*.

Capacity. Results from 1,000 simulated 800-borrower books per default rate, drawn from the 4Q hold-out:

Book default rate	Defaulters	Recall in top 40	Cost at 40	Cost-optimal list (cost)	Flag nobody	Names above p*
1.0%	8	56%	105.7	37 (104.2)	160	~39
2.0%	16	55%	175.6	43 (174.8)	320	~80
4.1% (CRISIL 2017 all-issuer)	33	48%	367.7	149 (241.1)	660	~161

Expected cost vs list size

In a normal book the 40-name cap is essentially cost-optimal (0.5% penalty at 2%). In a stressed book it binds (+52% at 4.1%), but it is still 44% cheaper than no monitoring. More than 40 names above p* is itself a **portfolio-stress trigger**.

Workflow (`policy.md`):

1. Day 1: the system issues the ranked list and memos.
2. Days 2–10: analyst triage.
3. By day 30: deep review with the sector head.
4. Next sitting: credit committee. Humans approve every limit change.

Hard triggers escalate immediately: a rating cut to sub-investment grade, a payment delay or an auditor resignation. Names above p* outside the 40 go to an overflow list. Calibration is refreshed quarterly to the realised default rate, and the model is retrained yearly. **Given §3, the model score is advisory for Indian borrowers until an India-trained model is validated.**

7. What we fixed in the earlier version (audit)

Our earlier CreditWatch build claimed 60% Indian recall at 4 quarters. The audit found that this number did not hold up, and the commit history shows each fix:

Issue found	Fix
Four defaulters (IL&FS, DHFL, Bhushan, Sintex) had round-number “reconstructed” rows, not filings	Replaced with Screener statements; the old rows are kept for audit and never used
Event dates were late milestones (Jet grounding, DHFL RBI supersession)	Earliest documented default, each sourced
Production model trained on the 5-year-horizon file and used for 4Q/8Q claims	Lead-matched 4Q/8Q models
Native-NaN model could read “missing = bankrupt”	Fold-safe median imputation
Missing COGS, inventory, receivables and cash were treated as 0 (e.g. 100% gross margin)	Left missing
Soft-signal dates were approximate, with no URLs	Five verified rating actions with URLs
Dashboard showed hard-coded results when artifacts were missing	Shows only computed values
A test deleted the real evaluation outputs	Backs up and restores them

8. Testing

- **Unit:** ratio mapping, missing-not-zero, annualisation, imputer neutrality, Wilson / peer-cutoff maths, hand-calculated Z''/M/F, monotonicity and clamp (v2), frozen-config tamper detection.
- **Data:** every event and signal sourced; every balance sheet balances; peers listed and covered.
- **Integration:** the point-in-time checks on the real panel; the summary must equal a recomputation from the scored rows; evaluation refuses edited weights; the synthetic end-to-end run through the leakage guard; 12 API endpoint tests through FastAPI's TestClient.
- **Totals: 40 passed.** The live FastAPI server (6 endpoints return 200), the Streamlit app (health OK) and the React production build (`npm run build`) were also smoke-tested.

9. Limitations

- The benchmark has no calendar time.
- 10 defaulters means wide intervals (0/10 has a 28% upper bound).
- Screener figures are restated and condensed.
- Standalone statements miss group stress.
- Peers stand in for a full 800-firm point-in-time universe.
- Survivorship in peer selection.
- No lender-specific (ALM) module.
- Alok, Bhushan and Coffee Day may have earlier undocumented payment stress, which would make their lead times shorter than shown.

Appendix: sources and reproduction

- **Benchmark:** UCI Polish Companies Bankruptcy, https://archive.ics.uci.edu/dataset/365/polish+companies+bankruptcy+data
- **Base-rate range:** CRISIL Default Study 2017, https://www.crisilratings.com/content/dam/crisil/our-analysis/publications/default-study/CRISIL-Default-Study-2017.pdf
- **Event and rating sources** (full URLs in `data/indian/events.csv` and `soft_signals.csv`): Business Standard (Jet, DHFL, Coffee Day, Alok, Reliance Capital ratings), Outlook Business (Reliance Capital default), Deccan Herald (Future Retail default), BloombergQuint (RCom, DHFL rating), CARE press releases (ITNL 18 Jul and 28 Sep 2018, Sintex 12 Jun 2019, Future Retail 13 May 2020), Axis Trustee notice (Bhushan Steel).
